

CYBERSECURITY

Security that survives an audit.

Most breaches exploit architecture, not zero-days.

EMALITE.COM

FLYER

We start from where your data actually sits and who genuinely needs it, then build the boundary around that – segmentation between zones, inspection where it counts, access decided by identity rather than by which port someone plugged into. Then we test it, because a control nobody has exercised is a control nobody should rely on.

- ◆ Firewall rule bases rationalised – and explicable, rule by rule
- ◆ Segmentation with a named, testable boundary
- ◆ Identity-aware access for users and machines
- ◆ Architecture review and vulnerability assessment
